

# Globus Toolkit

## Introduction

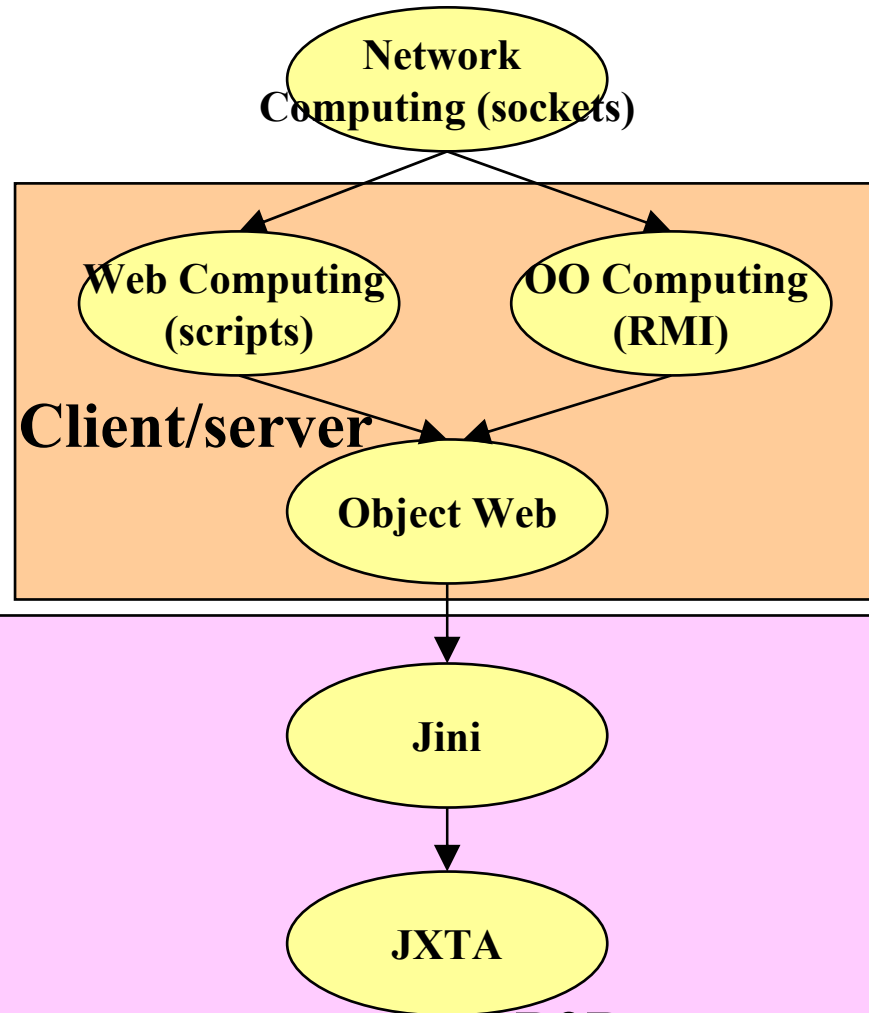

The Globus Project Team

<http://www.globus.org>

# Progress to Grid and P2P systems

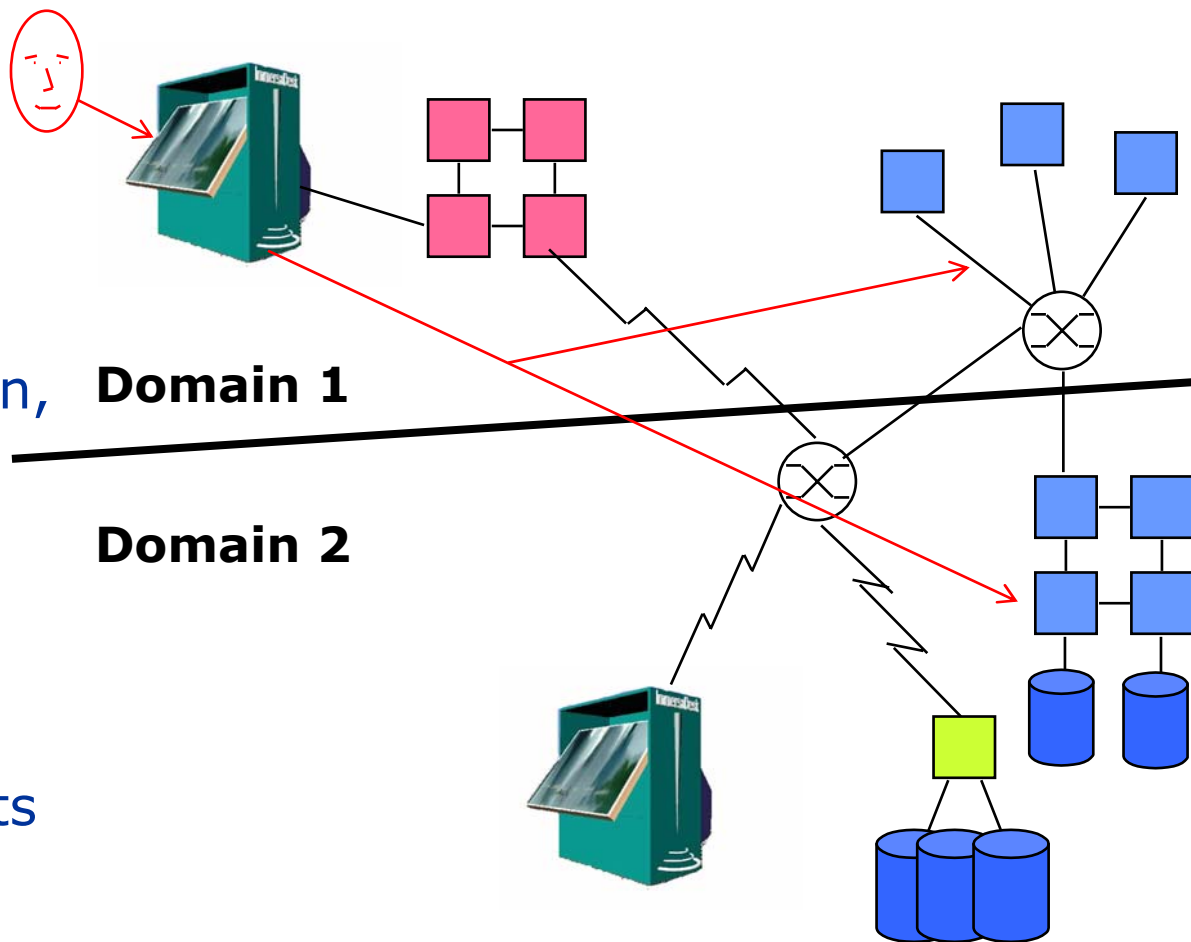

**Grid systems**

**P2P systems**

# Issues

- Authenticate once
- Specify simulation (code, resources, etc.)
- Locate resources
- Negotiate authorization, acceptable use, etc.
- Acquire resources
- Initiate computation
- Steer computation
- Access remote datasets
- Collaborate on results
- Account for usage

# Architectural Approaches

- Distributed systems: DCE, CORBA, Jini, etc.
  - ◆ Rich functionality eases app development
  - ◆ Complexity hinders deployment
    - especially in absence of global control
  - ◆ Performance difficulties
- Internet/Web Protocols and Tools
  - ◆ Simple protocols facilitate deployment
  - ◆ Missing functionality hinders app development
  - ◆ Performance difficulties

# Standards & Commodity Tech

- Where appropriate, exploit standards and commodity technology in core infrastructure
  - ◆ LDAP, SSL/TLS, X.509, GSS-API, http, ftp, XML, SOAP, etc.
  - ◆ Provides leverage
- Interface with other common standards
  - ◆ CORBA, Java/Jini, DCOM, Web, etc
  - ◆ While our core infrastructure may not be built on one of these distributed architectures, we can and must cleanly interface with them

# The Globus Project

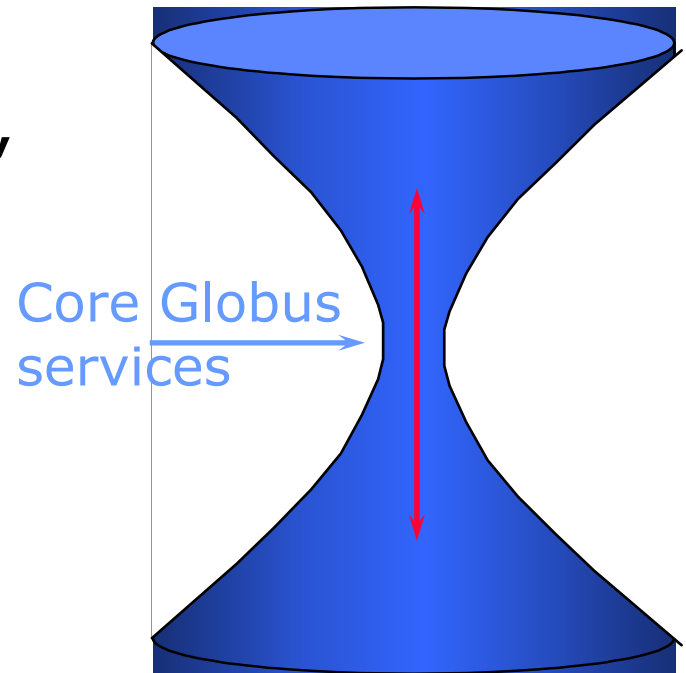

- Basic research in grid-related technologies
  - ◆ Resource & data management, security, QoS, policy, communication, adaptation, etc.
- Development of Globus Toolkit
  - ◆ Core services for grid-enabled tools & apps
- Construction of production grids & testbeds
  - ◆ Multiple deployments to distributed organizations for production & prototyping
- Application experiments
  - ◆ Distributed applications, tele-immersion, etc.

# Globus Approach: Hourglass

- Focus on architecture issues
  - ◆ Propose set of core services as basic infrastructure
  - ◆ Use to construct high-level, domain-specific solutions
- Design principles
  - ◆ Keep participation cost low
  - ◆ Enable local control
  - ◆ Support for adaptation
  - ◆ “IP hourglass” model

## Applications

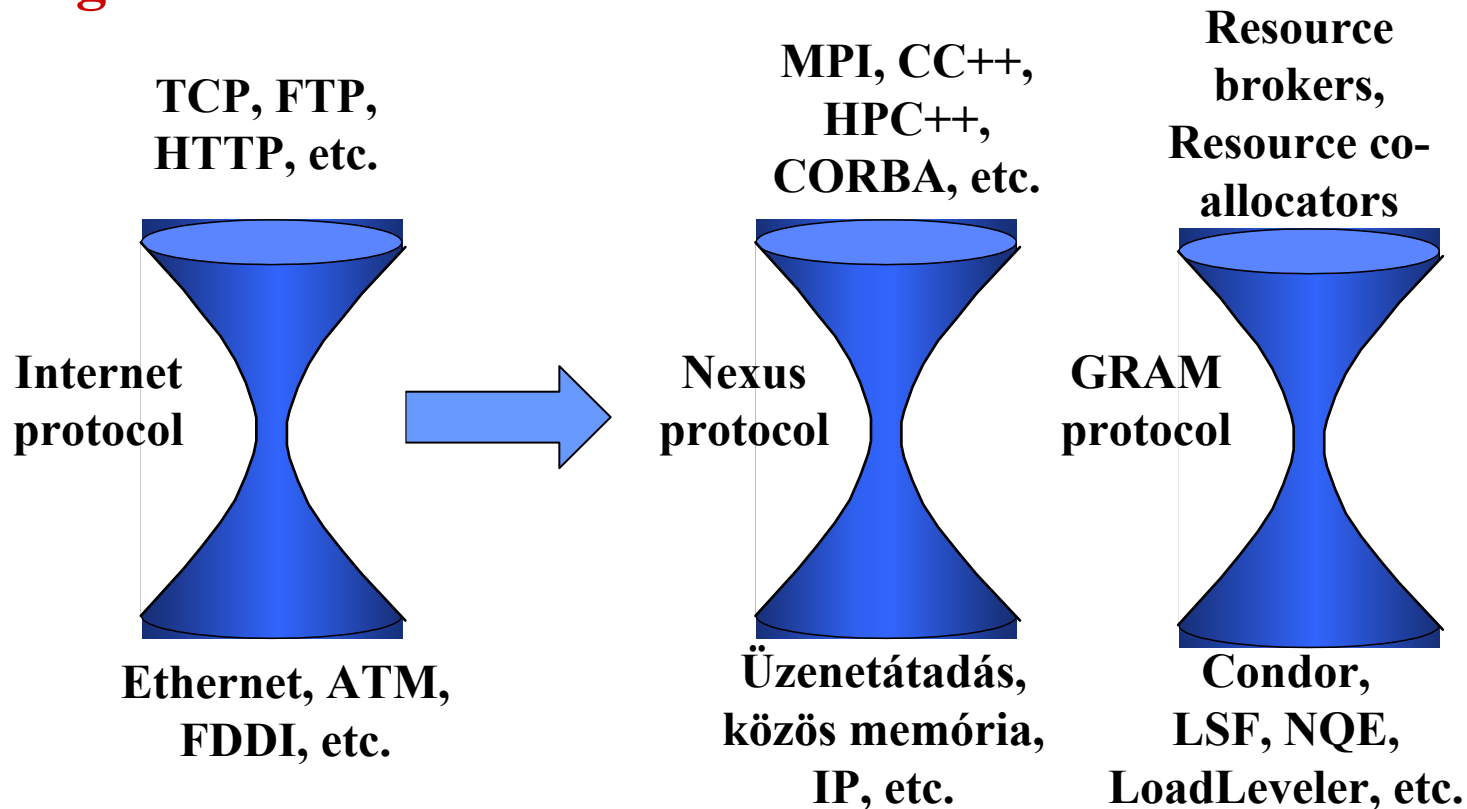

Diverse global services

Local OS

# Globus Approach: Hourglass

## High-level services

## Low-level tools

# Globus Toolkit Grid Services

- Security (GSI)
- Resource management (GRAM)
- Information services (MDS)
- Remote file management (GASS)
- Communication (I/O, Nexus)
- Process monitoring (HBM)

# Other Globus Project Grid Services

- Coming Soon

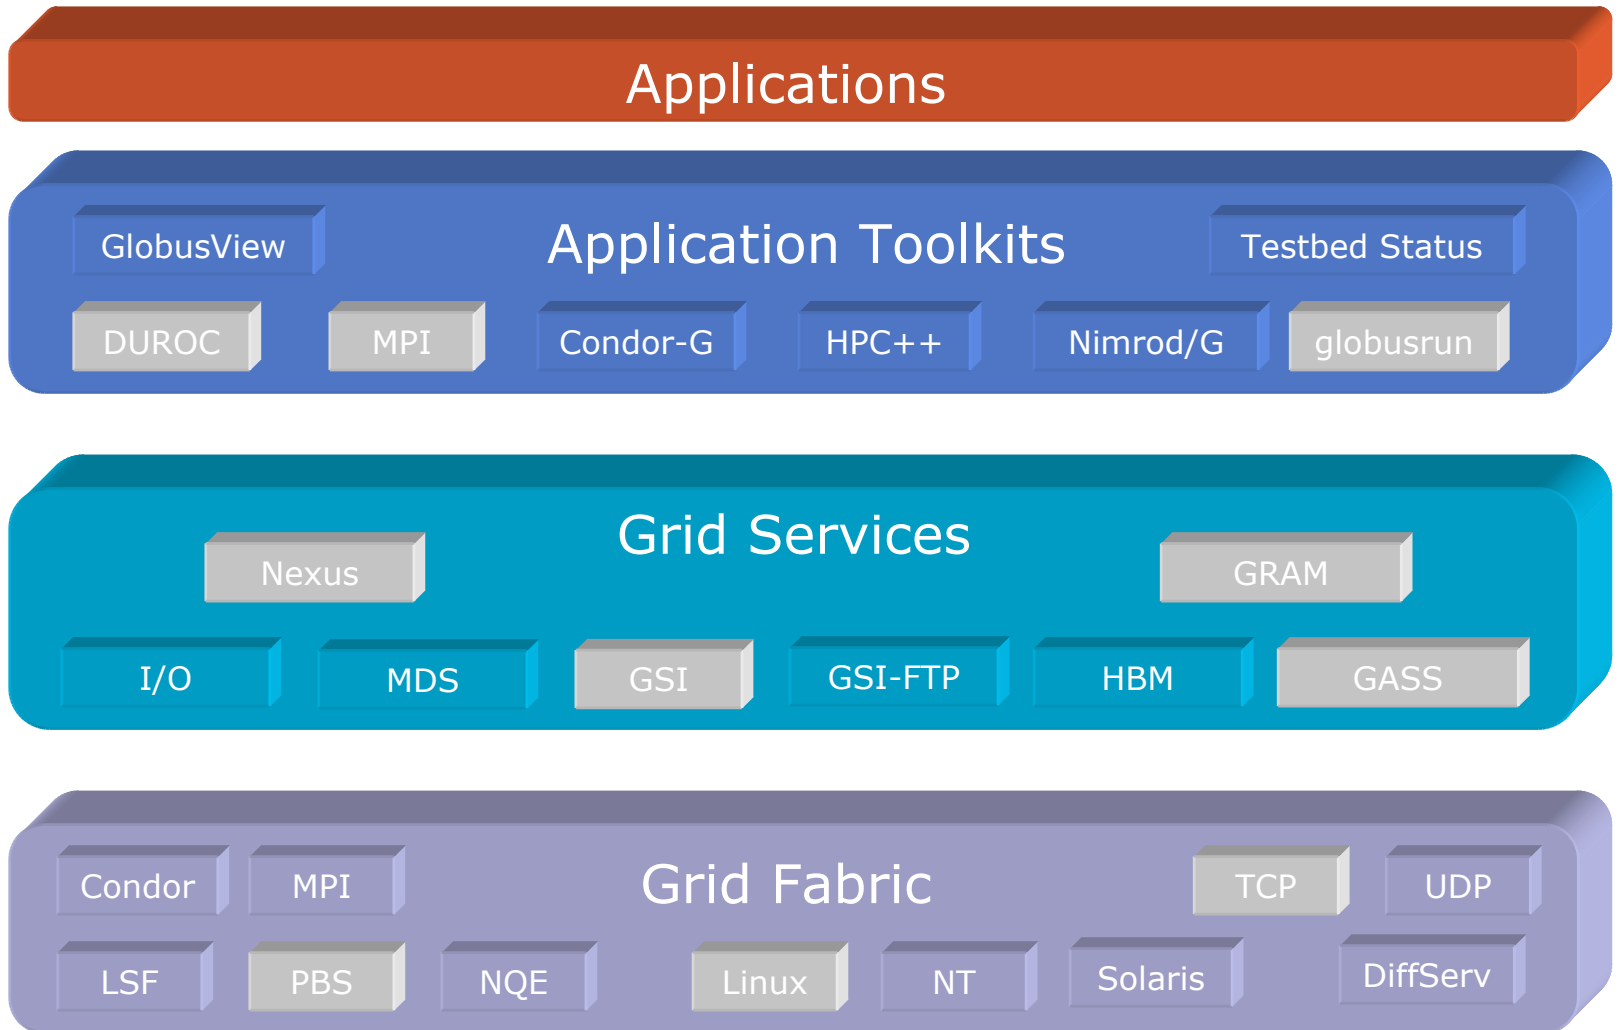

- ◆ Data transfer (GSI-FTP)
- ◆ Replica Management

<http://www.globus.org/datagrid>

- Experimental Prototypes

- ◆ Advanced Reservations & QoS (GARA)
- ◆ Distributed Events & Logging

# Layered Architecture

# The Need for Information System

- System information is critical to operation of the grid and construction of applications
  - ◆ How does an application determine what resources are available?
  - ◆ What is the “state” of the computational grid?
  - ◆ How can we optimize an application based on configuration of the underlying system?
- We need a general information infrastructure to answer these questions

# Using Information for Resource Brokering

"10 GFlops, EOS data, 100 Mb/sec -- for 20 mins"

Info service:  
location + selection

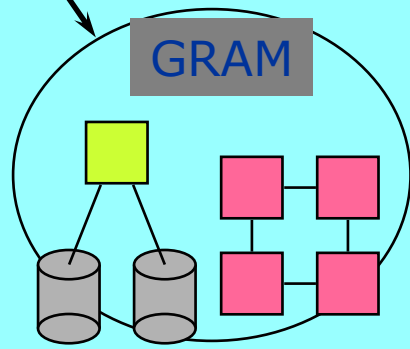

"20 Mb/sec"  
Globus Resource Allocation Managers

"What computers?"  
"What speed?"  
"When available?"

"50 processors + storage from 10:20 to 10:40 pm"

Fork  
LSF  
EASYLL  
Condor  
etc.

# Examples of Useful Information

- Characteristics of a compute resource
  - ◆ IP address, software available, system administrator, networks connected to, OS version, load
- Characteristics of a network
  - ◆ Bandwidth and latency, protocols, logical topology
- Characteristics of the Globus infrastructure
  - ◆ Hosts, resource managers

# Grid Information Service

- Provide access to **static** and **dynamic** information regarding system components
- Requirements and characteristics
  - ◆ **Uniform**, flexible access to information
  - ◆ **Scalable**, efficient access to dynamic data
  - ◆ Access to multiple information sources
  - ◆ **Decentralized maintenance**

# The Globus Toolkit

## Metacomputing Directory Service

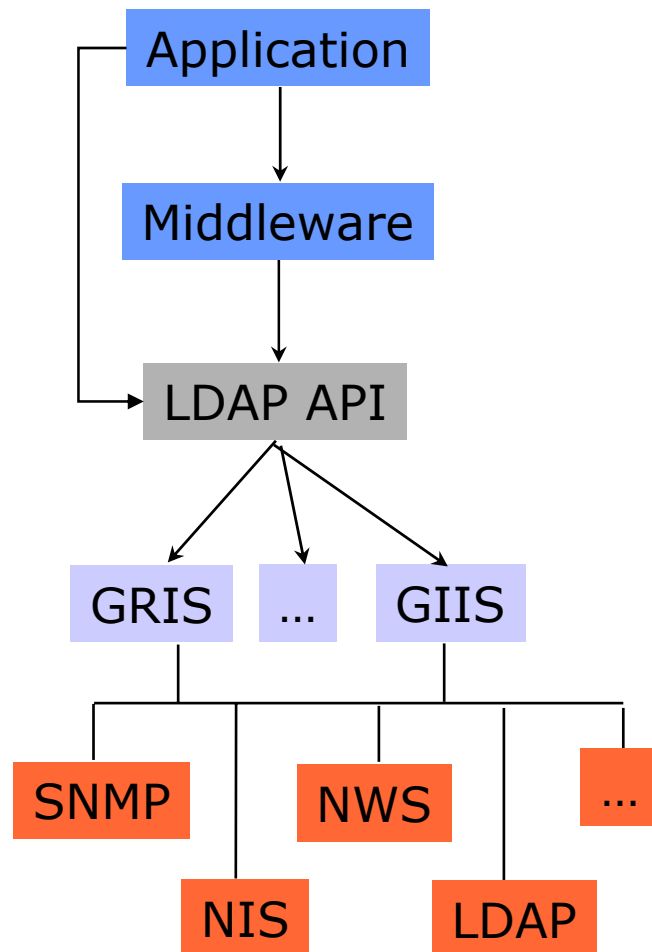

- Store information in distributed directories
  - ◆ Directory stored in collection of LDAP servers
  - ◆ Each server optimized for particular function
- Directory can be updated by
  - ◆ Information providers and tools
  - ◆ Applications (i.e., users)
  - ◆ Backend tools which generate info on demand
- Information dynamically available to
  - ◆ Tools
  - ◆ Applications

# Directory Service Functions

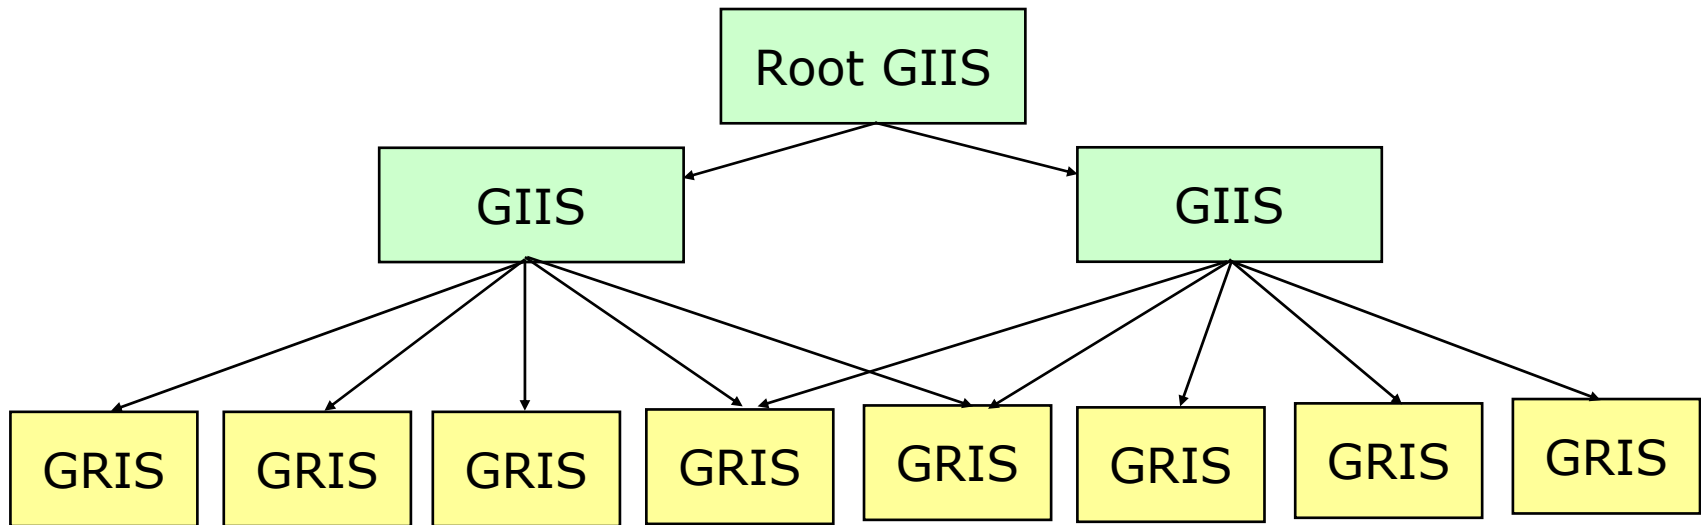

- White Pages
  - ◆ Look up the IP number, amount of memory, etc., associated with a particular machine
- Yellow Pages
  - ◆ Find all the computers of a particular class or with a particular property
- Temporary inconsistencies are often considered okay
  - ◆ In a distributed system, you often do not know the state of a resource until you actually use it
  - ◆ Information is often used as “hints”

# MDS Approach

- Based on **LDAP**
  - ◆ Lightweight Directory Access Protocol v3 (LDAPv3)
  - ◆ Standard data model
  - ◆ Standard query protocol
- **Globus specific schema**
  - ◆ Host-centric representation
- **Globus specific tools**
  - ◆ GIIS (Grid Index Info Server)
  - ◆ GRIS (Grid Resource Info Server)
  - ◆ Data discovery, publication,...

# Hierarchical Grid Resource Discovery System

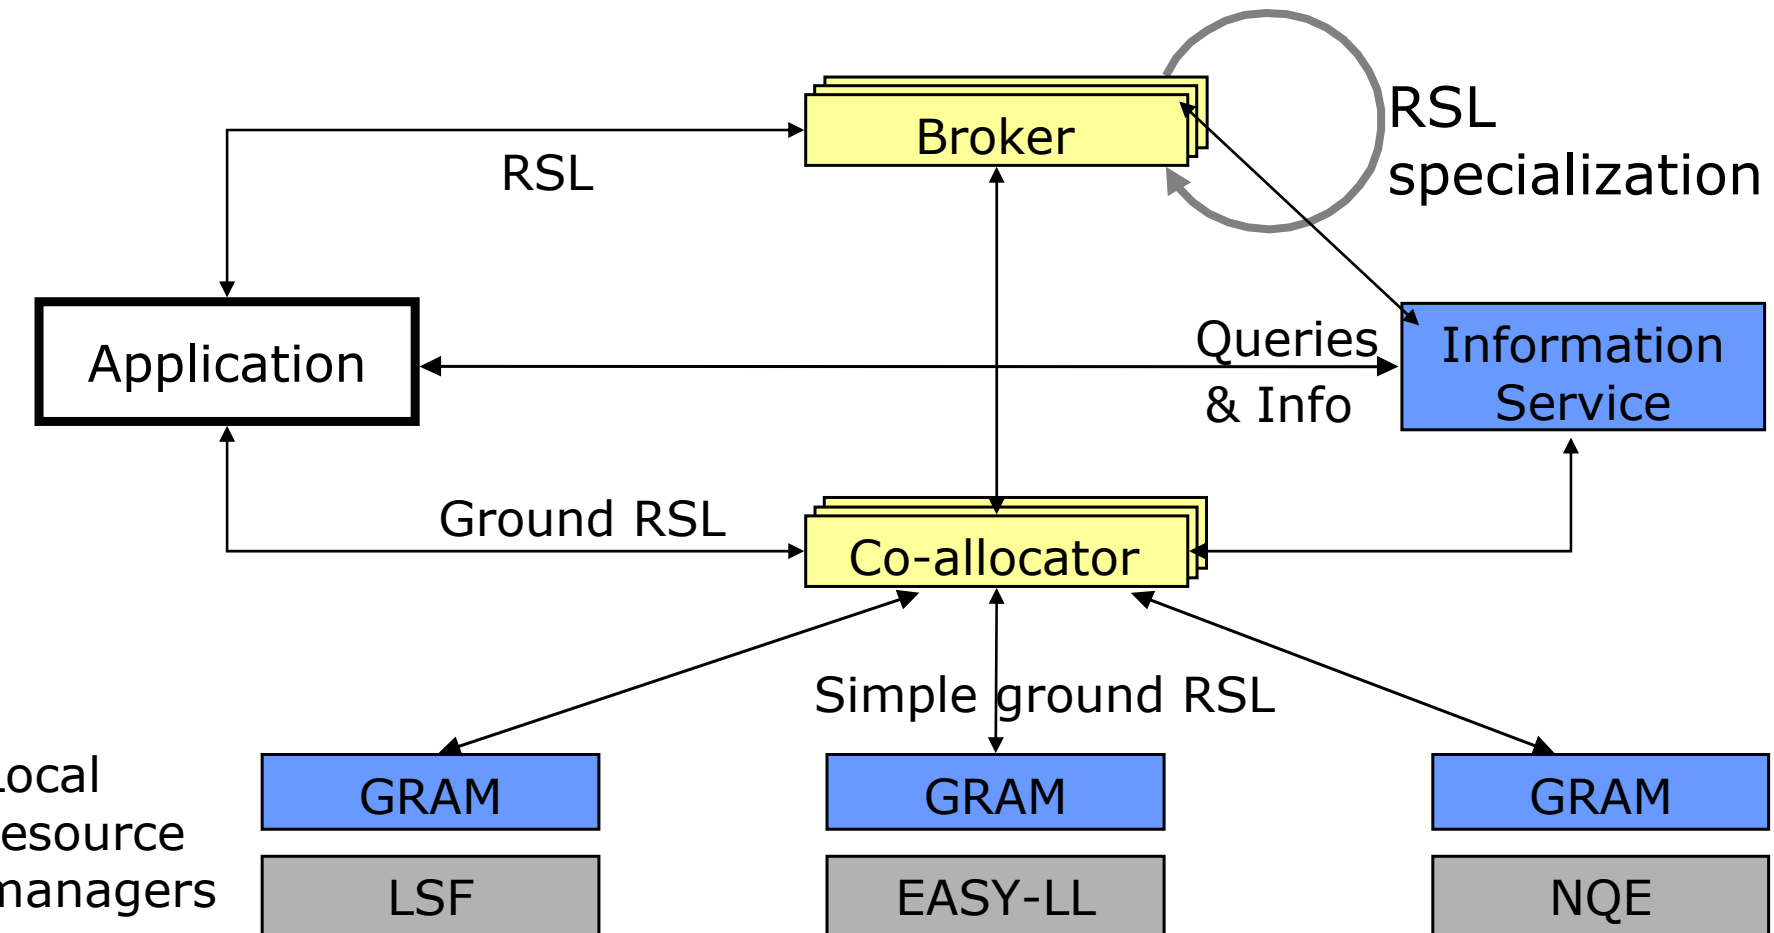

1. Once the client found the root service, it submits its query to it
2. The root GIIS returns a set of possible candidates, using the static attributes
3. The client uses this set of information to narrow the search to a child GIIS
4. The client uses the new set of information to narrow the search to a GRIS and to obtain dynamic information of the selected resource

# Components of Resource Management

- Resource Specification Language (**RSL**) is used to communicate requirements
- The Globus Resource Allocation Manager (**GRAM**) API allows programs to be started on remote resources
- A layered architecture allows application-specific **resource brokers** and **co-allocators** to be defined in terms of GRAM services

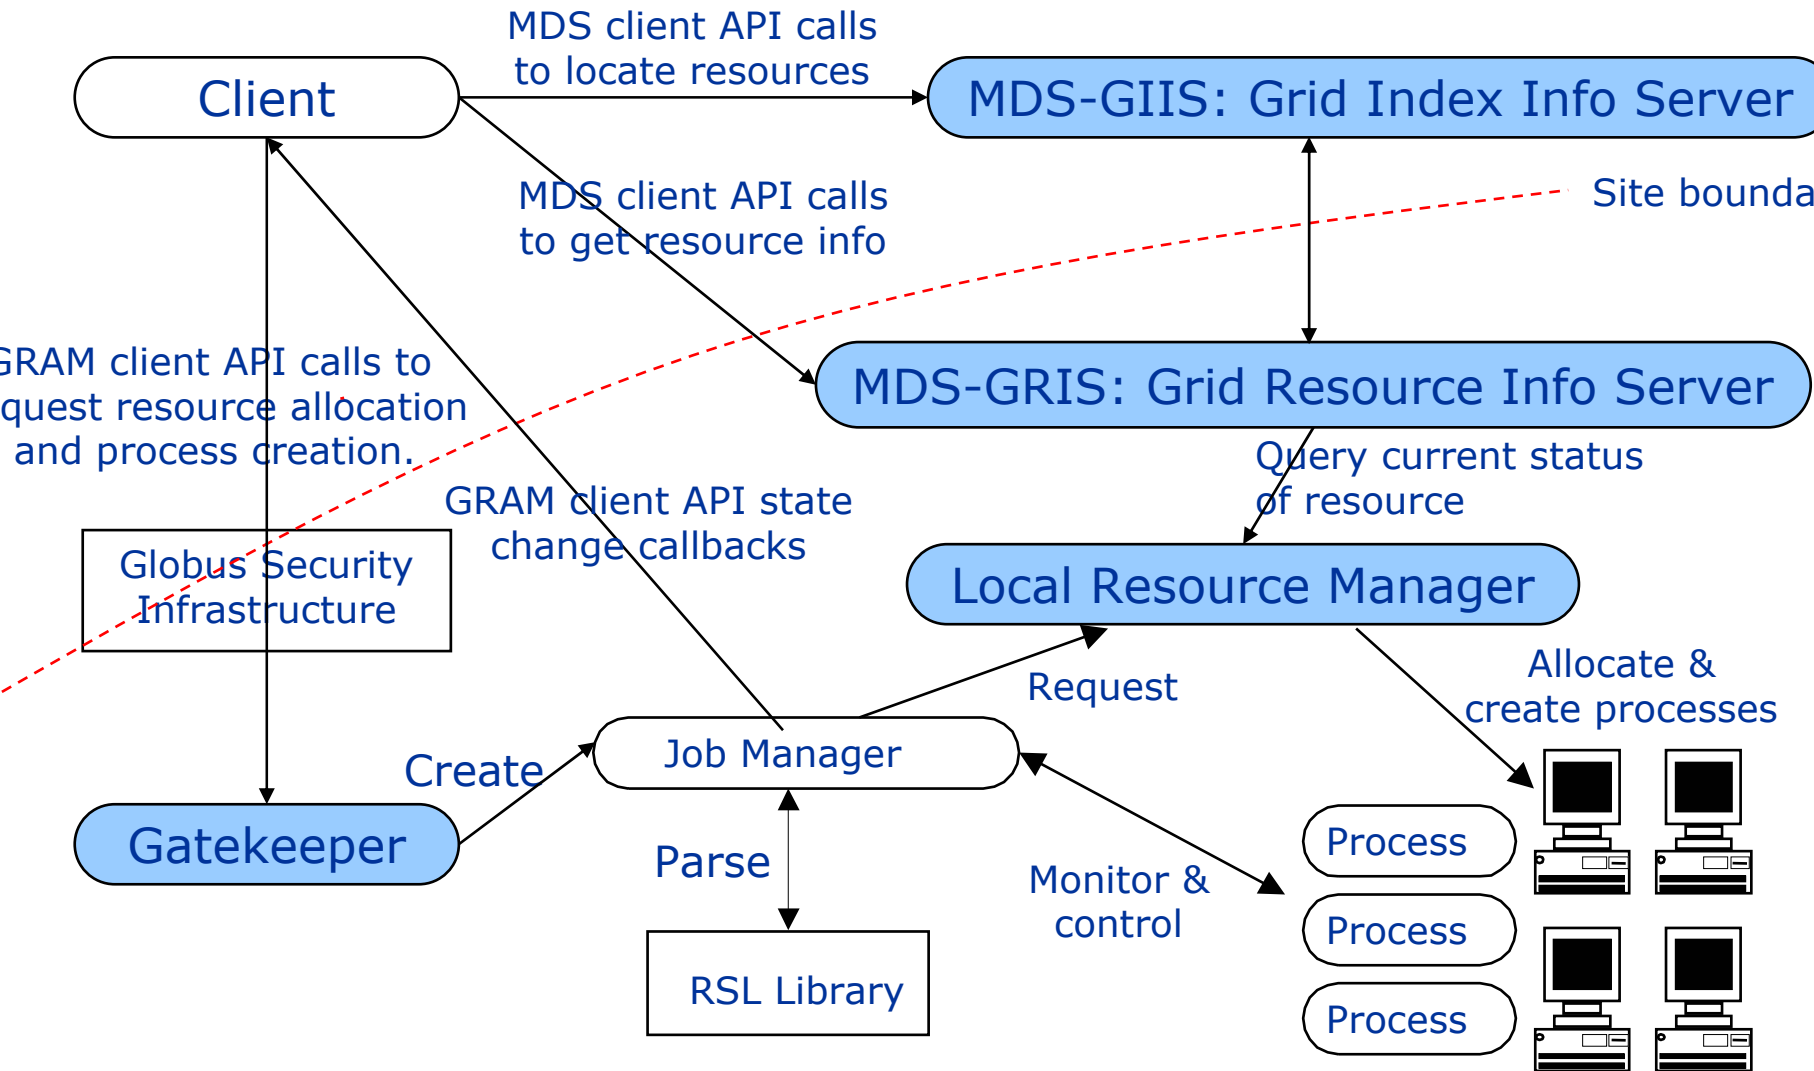

# Resource Management Architecture

# Globus Resource Allocation Manager (GRAM)

- Processing RSL specifications representing resource requests, by
  - ◆ Either creating the process(es) that satisfies the request
  - ◆ Or denying that request
- Periodically updating the MDS with info about the current status of the resources it manages
- Enabling remote job monitoring and management

# GRAM Components

GRAM: 2119

GRIS: 2135

GIIS port (system administrator can set up)

GASS port (user can set up)

Gatekeeper:

When a request arrives on a Globus port, the Gatekeeper checks the security aspects. If they are fine, the Gatekeeper initiates the requested service on the port. These services are:

- MDS
- GRAM
- GASS

# Resource Specification Language

- Common notation for exchange of information between components
  - ◆ Syntax similar to MDS/LDAP filters
- RSL provides two types of information:
  - ◆ Resource requirements: Machine type, number of nodes, memory, etc.
  - ◆ Job configuration: Directory, executable, args, environment
- API provided for manipulating RSL

# RSL Syntax

- Elementary form: parenthesis clauses
  - ◆ (attribute op value [ value ... ] )
- Operators Supported:
  - ◆ <, <=, =, >=, >, !=
- Some supported attributes:
  - ◆ executable, arguments, environment, stdin, stdout, stderr, resourceManagerContact, resourceName
- Unknown attributes are passed through
  - ◆ May be handled by subsequent tools

## Constraints: "&"

- For example:

"Create 5-10 instances of **myprog**, each on a machine with at least 64 MB memory that is available to me for 4 hours"

**& (count >= 5) (count <= 10)**

**(max\_time=240) (memory >= 64)**

**(executable=myprog)**

## Disjunction: “|”

- For example:
- Create 5 instances of myprog on a machine that has at least 64MB of memory, or 10 instances on a machine with at least 32MB of memory

```
& (executable=myprog)  
  ( | (&(count=5)(memory>=64))  
    (&(count=10)(memory>=32)))
```

## Multirequest: “+”

- A multirequest allows us to specify multiple resource needs, for example

+ (& (count=5)(memory >=64)

(executable=p1))

(&(network=atm) (executable=p2))

- ◆ Execute 5 instances of p1 on a machine with at least 64M of memory
- ◆ Execute p2 on a machine with an ATM connection
- Multirequests are central to co-allocation

# Co-allocation

- Simultaneous allocation of a resource set
  - ◆ Handled via optimistic co-allocation based on free nodes or queue prediction
  - ◆ In the future, advance reservations will also be supported
- **globusrun** and **globus-job-\*** will co-allocate specific multi-requests
  - ◆ Uses a Globus component called the Dynamically Updated Request Online Co-allocator (DUROC)

# A Co-allocation Multirequest

```
+( & (resourceManagerContact=  
  "flash.isi.edu:754:/C=US/.../CN=flash.isi.edu-fork")  
  (count=1)  
  (label="subjob A")  
  (executable=my_app1)  
)  
( & (resourceManagerContact=  
  "sp139.sdsc.edu:8711:/C=US/.../CN=sp097.sdsc.edu-lsf")  
  (count=2)  
  (label="subjob B")  
  (executable=my_app2)  
)
```

Different counts

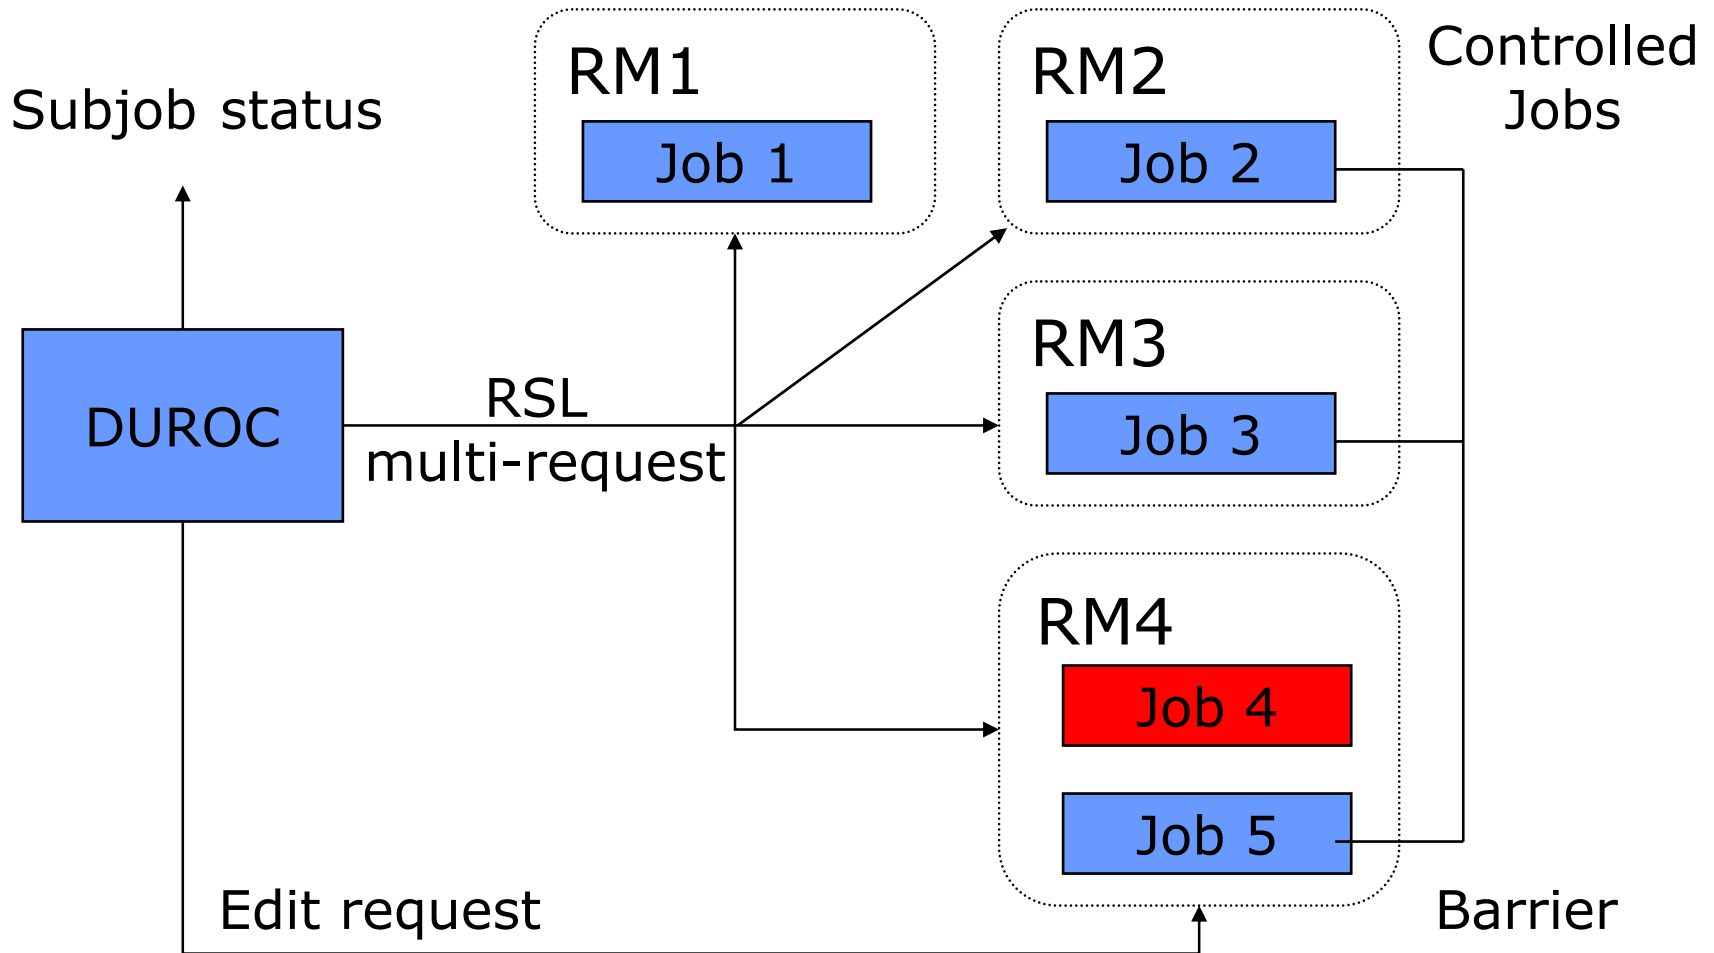

Different resource managers

Different executables

# DUROC Functions

- Submit a multi-request
- Edit a pending request
  - ◆ Add new nodes, edit out failed nodes
- Commit to configuration
  - ◆ Delay to last possible minute
  - ◆ Barrier synchronization
- Initialize computation
  - ◆ Bootstrap library
- Monitor and control collection

# DUROC Architecture

# Global Access to Secondary Storage (GASS)

GASS enables access to remote files and executables

## (a) GASS file access API

- ◆ Replace open/close with `globus_gass_open/close`; read/write calls can then proceed directly

## (b) RSL extensions

- ◆ URLs used to name executables, stdout, stderr

## (c) Remote cache management utility

## (d) Low-level APIs for specialized behaviors

# GASS Architecture

Execution machine

```

main( ) {
  fd = globus_gass_open(...)
  ...
  read(fd,...)
  ...
  globus_gass_close(fd)
}
  
```

(a) GASS file access API

Submit machine

&(executable=https://...)

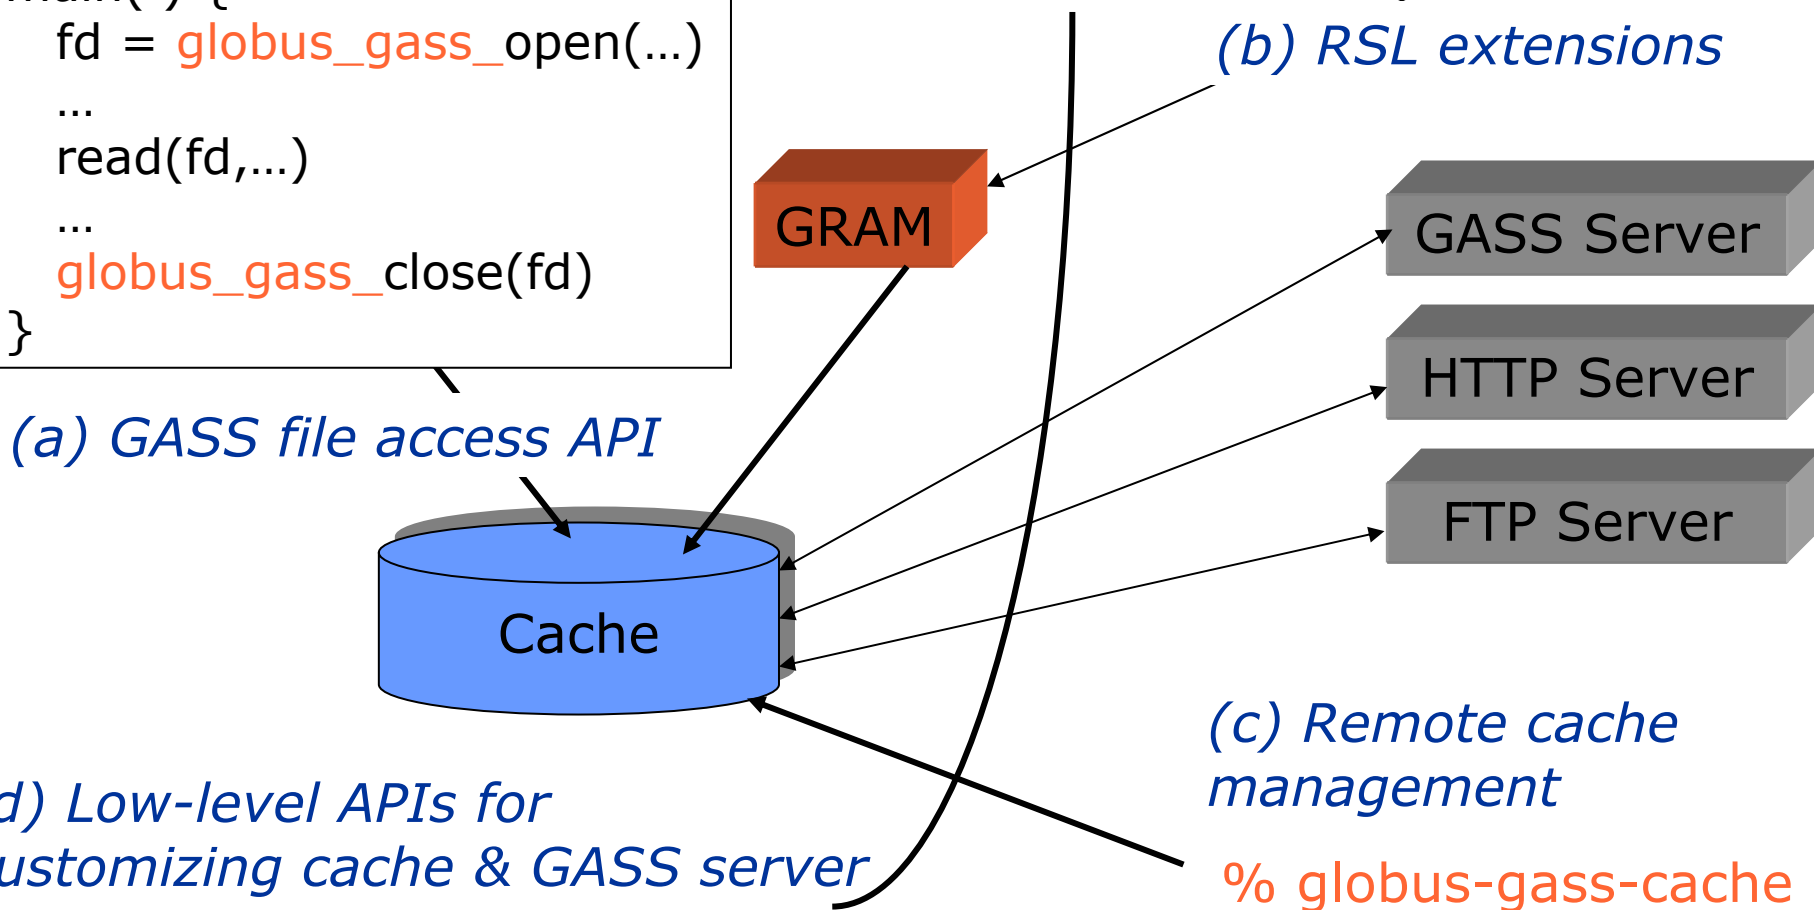

(b) RSL extensions

(c) Remote cache management

(d) Low-level APIs for customizing cache & GASS server

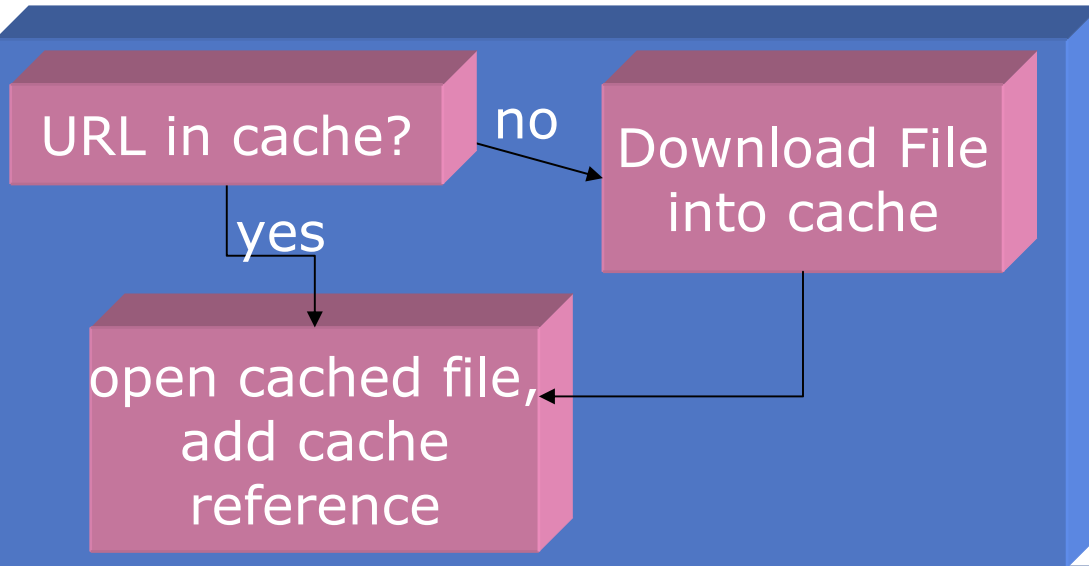

% globus-gass-cache

# GASS/RSL Example

```
&(executable=https://quad:1234/~myexe)  
  (stdin=https://quad:1234/~myin)  
  (stdout=/home/bester/output)  
  (stderr=https://quad:1234/dev/stdout)
```

# globus\_gass\_open()/close()

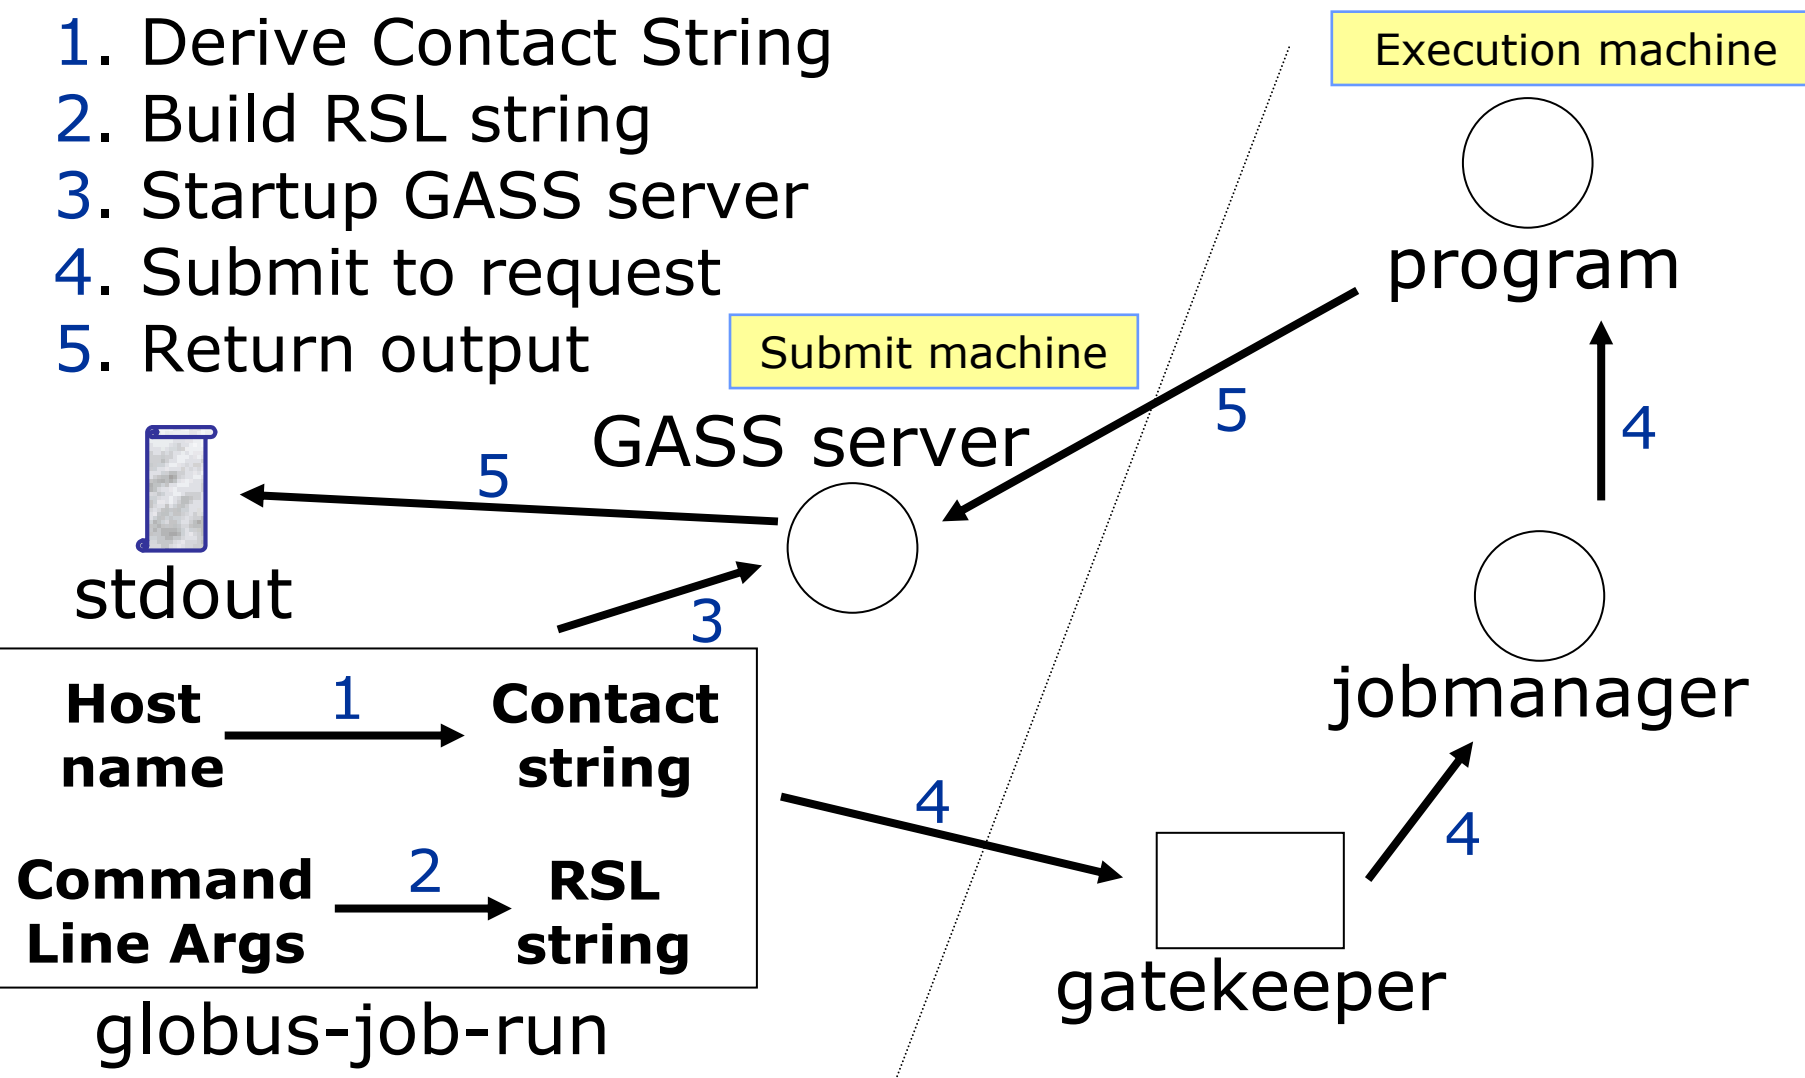

globus\_gass\_open()

globus\_gass\_close()

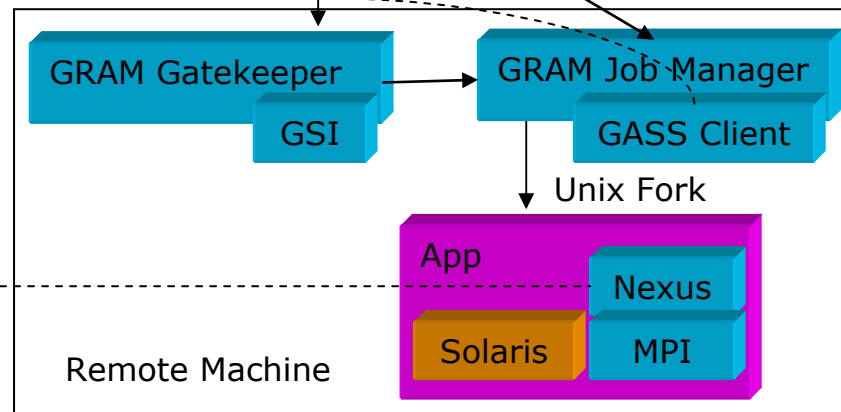

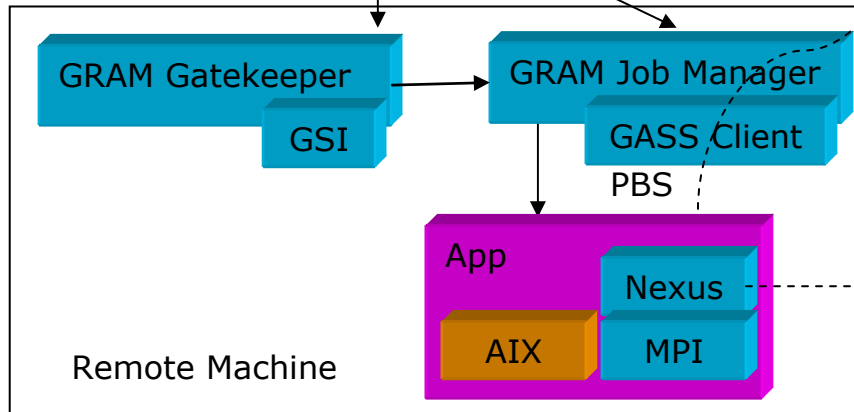

# GRAM & GASS: Putting It Together

1. Derive Contact String
2. Build RSL string
3. Startup GASS server
4. Submit to request
5. Return output

# Globus Components In Action

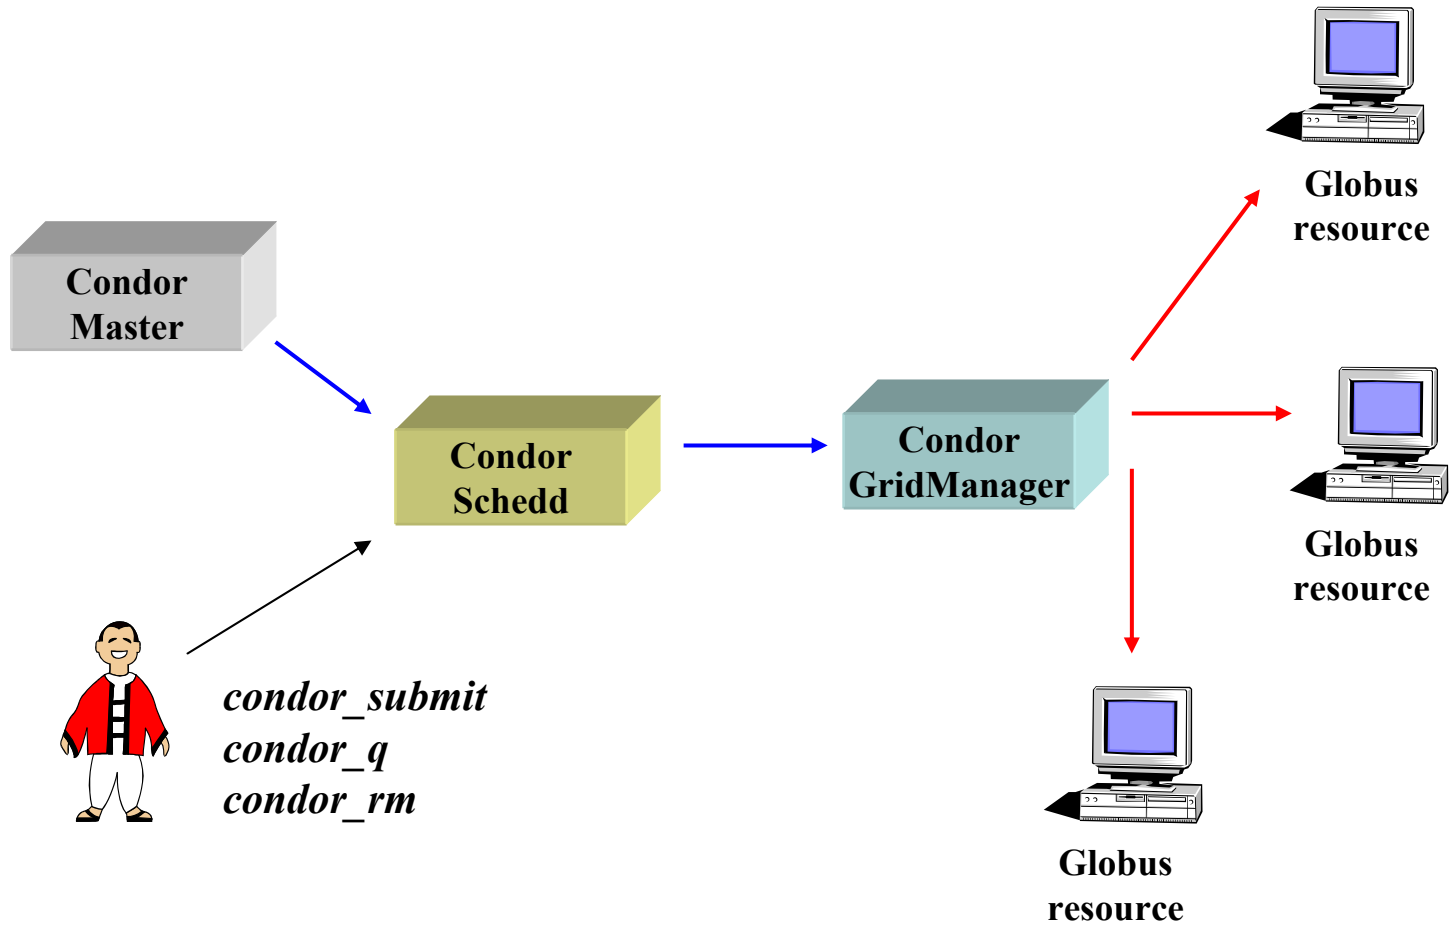

# What is Condor-G?

- Condor-G is a Personal-Condor enhanced with Globus services
- It knows how to speak to Globus resources via GRAM
- It can be used to submit jobs to remote Globus resources
- It makes Condor keep track of their progress

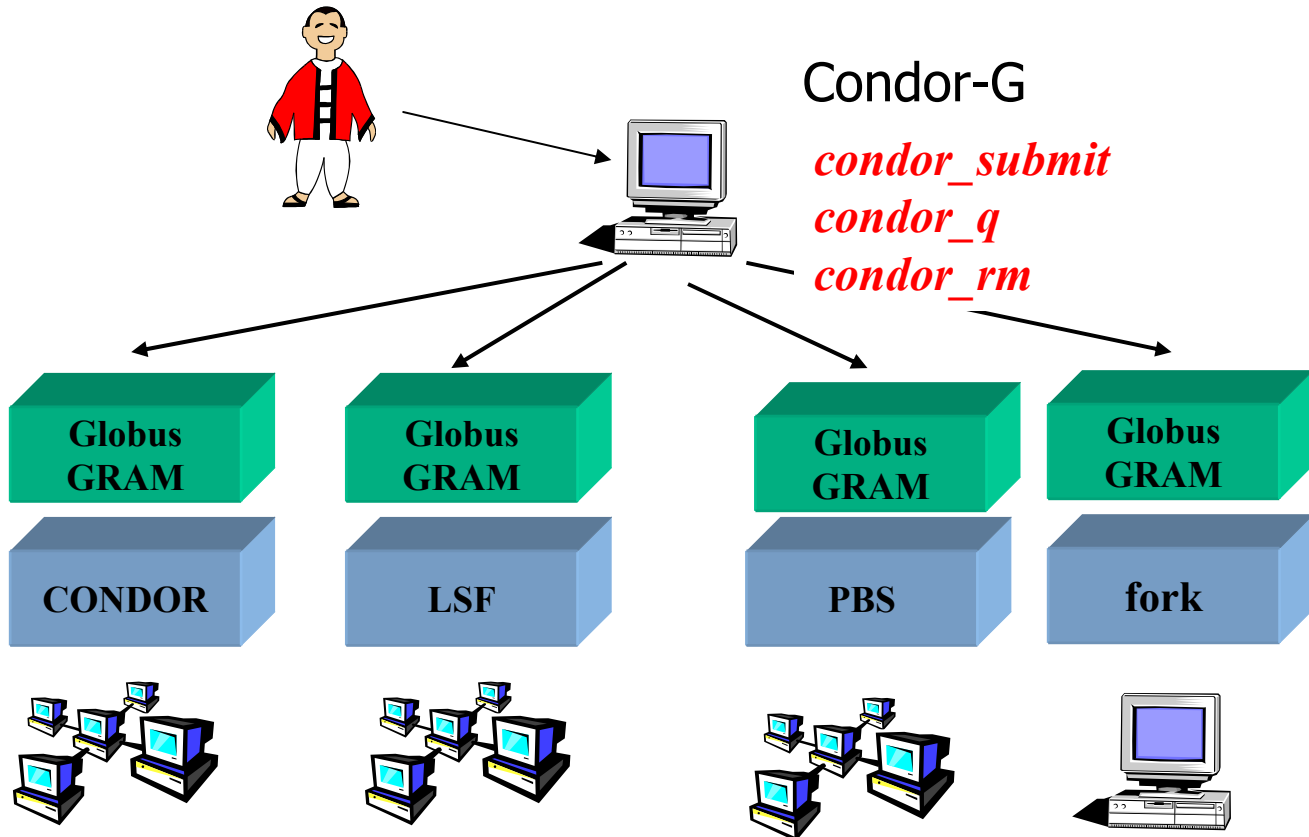

# Condor-G: Condor for the Grid

- Condor is a high-throughput scheduler
- Condor-G uses Globus Toolkit libraries for:
  - ◆ Security (GSI)
  - ◆ Managing remote jobs on Grid (GRAM)
  - ◆ File staging & remote I/O (GSI-FTP)
- Grid job management interface & scheduling
  - ◆ Robust replacement for Globus Toolkit programs
    - To implement a reliable, crash-proof, checkpointable job submission service
  - ◆ Supports single or high-throughput apps on Grid
    - Personal job manager which can exploit Grid resources

# The Use of Condor-G

# Condor-G as user job submission service

# The Grid:

## Blueprint for a New Computing Infrastructure

I. Foster, C. Kesselman (Eds), Morgan Kaufmann, 1999

- Available July 1998;  
ISBN 1-55860-475-8
- 22 chapters by expert authors including Andrew Chien, Jack Dongarra, Tom DeFanti, Andrew Grimshaw, Roch Guerin, Ken Kennedy, Paul Messina, Cliff Neuman, Jon Postel, Larry Smarr, Rick Stevens, and many others
